Arrays

Contents

- Introduction
- Arrays
- Indexing Using Registers
- Sequential Search
- Complete Programs
- Summary
- Practical Works
- Assignments

Introduction

- From an assembly language programmer's perspective, a two-dimensional array is a high-level abstraction of a one-dimensional array.
- There exist two methods of arranging rows and columns in memory: row-major and column-major orders as shown in figure.

Array Declaration

- There are a couple of different ways to declare an array based on the data and the needs of the programmer.
- The simplest way to declare an array is to list memory location after memory location.
- Note that number is declared as an sdword which takes up 4 bytes.

```
number sdword 2  
result    sdword 7
```

Array Declaration (Cont.)

- It is also possible to create an array as follow.
- It should be noticed that the subsequent memory locations do not have variable names attached to them.

```
numary sdword 2  
        sdword 5  
        sdword 7
```

Array Declaration (Cont.)

- MASM has an easier way to declare the above on just one line.
- The directive `sdword` need to appear only once.
- Each of the entries would appear on the same line and each separated by a comma as follow.

```
numary sdword 2,5,7
```

Array Initialization

- If each element of an array can be initialized to the same number, such as 0, it can be declared as follow:

```
zeroary sdword 0,0,0
```

- If each memory location in the array did not need to be initialized, it can be declared as follow:

```
empary sdword ?,?,?
```

Array Initialization (Cont.)

DUP Operator

- If there were hundreds of elements needed to be initialized, then clearly, the above method would be cumbersome.
- Instead, the DUP operator is very convenient.
- The above would be rewritten as follows:

```
zeroary sdword 3 dup(0)  
empary sdword 3 dup(?)
```

Accessing Array Elements

- Assume that the last element of the previously declared numary needed to be moved to the first element of numary.
- Arrays always start with the zeroth element.
- The C equivalent of this operation would be:

```
numary[0] = numary[2];
```

Accessing Array Elements (Cont.)

- The equivalent assembly code would be as follow.

```
mov eax,numary+8      ; load eax with third element  
mov numary+0,eax     ; store eax in first element
```

- Here, 8 is added to numary because the third element is in the thirdth memory location and each memory location is 4 bytes long.

Indexing Using Base Register

- In assembly language, indexing is accomplished using registers.
- The ebx register is known as the base register and it is very useful when indexing arrays.
- Although it is a register, it is used much like an index variable in the C programming language.

Indexing Using Base Register (Cont.)

- Let's consider a MASM code segment to calculate the sum of all the elements of an array.
- Assume that the array called numary already contains values and the equivalent C code is as shown below:

```
int numary[3] = {2,5,7};  
sum = 0;  
for(i=0; i<3; i++)  
sum += numary[i];
```

- In the above C code, the variable i is being used both as a loop counter and as an index.

Indexing Using Base Register (Cont.)

- In assembly language, two separate registers need to be used for a loop counter and an index.
- So, ebx is used for indexing and ecx is used for loop control.
- Note that a 4 needs to be added to the ebx register to access the next signed double word.

Indexing Using Base Register (Cont.)

- The resulting code is as follows:

```
numary sdword 2,5,7
sum    sdword ?
      mov sum,0           ; initialize sum to 0
      mov ecx,3          ; initialize ecx to 3
      mov ebx,0          ; initialize ebx to 0
      .repeat
      mov eax,numary[ebx] ; load eax with element of numary
      add sum,eax         ; add eax to sum
      add ebx,4           ; increment ebx by 4
      .untilcxz
```

Indexing Using Base Register (Cont.)

Example

- Write a MASM program for the following C program.

```
int arry[20],n,i;
printf("\n%s","Enter the number of integers to be input: ");
scanf("%d",&n);
if (n>0){
    for (i=0; i<n; i++){
        printf("\n%s","Enter an integer: ");
        scanf("%d",&arry[i]);
    }
    printf("\n%s\n\n","Reversed");
    for (i=n-1;i>=0;i--)
        printf("    %d\n\n",arry[i]);
}
else
    printf("\n%s\n\n","No data entered.");
```

Indexing Using Base Register (Cont.)

Example

- The following is a MASM code segment for the given C program.

```
.data
msg1fmt byte 0Ah,"%s",0
msg2fmt byte 0Ah,"%s",0Ah,0Ah,0
msg3fmt byte "%d",0Ah,0Ah,0
in1fmt  byte "%d",0
msg1    byte "Enter the number of integers to be input: ",0
msg2    byte "Enter an integer: ",0
msg3    byte "Reversed",0
msg4    byte "No data entered."
n       sdword ?
array   sdword 20 dup(?)
.code
INVOKE printf, ADDR msg1fmt,ADDR msg1
INVOKE scanf, ADDR in1fmt, ADDR n
mov ecx,n                ; initialize ecx to n
mov ebx,0                ; initialize ebx to 0
.if ecx>0
.repeat
push ecx                ; save ecx
INVOKE printf, ADDR msg1fmt, ADDR msg2
INVOKE scanf, ADDR in1fmt, ADDR array[ebx]
pop ecx                 ; restore ecx
add ebx,4               ; increment ebx by 4
.untilcxz
INVOKE printf, ADDR msg2fmt, ADDR msg3
mov ecx,n                ; initialize ecx to n
sub ebx,4               ; subtract 4 from ebx
.repeat
push ecx                ; save ecx
INVOKE printf, ADDR msg3fmt,array[ebx]
pop ecx                 ; restore ecx
sub ebx,4               ; decrement ebx by 4
.untilcxz
.else
INVOKE printf, ADDR msg2fmt, ADDR msg4
.endif
```

Indexing Using esi and edi Registers

- There exist two index registers called esi (source index register) and edi (destination index register).
- These registers are used more like pointers and they are very useful when manipulating strings.
- As a general rule, when retrieving data from memory, it is best to use the esi register because memory is the source from which the data is coming.
- When storing data back into memory, the edi register indicates the destination where the data will be placed.

Indexing Using esi and edi Registers (Cont.)

OFFSET Operator

- It is important to load the addresses when working with the arrays.
- This can be done by using the OFFSET operator.
- In a sense, using OFFSET is static and the address is calculated at assembly time.
- To load the address of one element of an array into one register, we can use the MOV instruction together with the OFFSET operator.

Indexing Using esi and edi Registers (Cont.)

OFFSET Operator

- The following code segment loads the address of the second element of the array numary into the esi register by using MOV and OFFSET operator.

```
mov esi,offset numary+4  
mov eax,[esi]
```

- If the square bracket around esi is omitted, then the value in the esi register will be transferred to the eax register.

Indexing Using esi and edi Registers (Cont.)

LEA Operator

- LEA stands for Load Effective Address.
- Using LEA is dynamic.
- With LEA, the address is calculated at run-time.
- Instead of using the MOV instruction with the word OFFSET, the LEA instruction can be used as follow.

```
lea esi,memory+4  
mov eax,[esi]
```

Indexing Using esi and edi Register (Cont.)

- The MASM code segment for calculating the sum of all the elements in an array can be implemented using the esi register as follows:

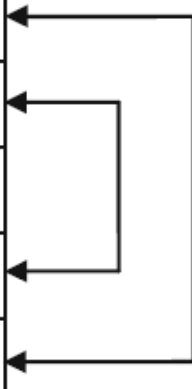

```
mov sum,0      ; initialize sum to zero
mov ecx,3      ; initialize ecx to 3
lea esi,numary+0 ; load the address of numary into esi
.repeat
mov eax,[esi]  ; move contents of where esi pointing to eax
add sum,eax    ; add eax to sum
add esi,4      ; increment esi by 4 to next element
.untilcxz
```

Indexing Using esi and edi Register (Cont.)

- Again, consider the MASM code segment to reverse the contents of the given array using the esi and edi registers.

n sdword 5
numary sdword 2,4,7,9,12

<u>Variable</u>	<u>Address</u>	<u>Contents</u>
n =	100	00000005
numary =	104	00000002
	108	00000004
	10C	00000007
	110	00000009
	114	0000000C

Indexing Using esi and edi Register (Cont.)

- Since there are an odd number of items, the middle element does not need to be swapped.
- Integer division can then be used to determine the number of items that need to be swapped.
- In this case, 5 divided by 2 is 2 and the two elements need to be exchanged.
- So, the loop should iterate a fixed number of times as $n/2$.

Indexing Using esi and edi Register (Cont.)

- The esi register is loaded with the address of the first element of the array, numary+0.
- To calculate the address of the last element of the array, the number of elements in the array is first decremented by 1 and then multiplied by 4.
- 5 minus 1 is 4, times 4 is 16, which when added to 104 is 120 in decimal or 114 in hexadecimal.

Indexing Using esi and edi Register (Cont.)

- Here is the MASM code segment to reverse the contents of the given array using the esi and edi registers.

```
mov ecx,n      ; load ecx with contents of n
sar ecx,1      ; divide ecx by 2, number of times to loop
lea esi,numary+0 ; load address of numary into esi
mov edi,esi    ; move contents of esi to edi
mov eax,n      ; load eax with contents of n
dec eax        ; decrement eax by one
sal eax,2      ; multiply eax by 4
add edi,eax    ; add eax to edi for ending address of array
.repeat
mov eax,[esi]  ; move contents where esi is pointing to eax
xchg eax,[edi] ; exchange eax and where edi is pointing
mov [esi],eax  ; move eax to where edi is pointing
add esi,4      ; add four to esi for next element
sub edi,4      ; subtract four from edi for next element
.untilcxz
```

Indexing Using esi and edi Register (Cont.)

LENGTHOF Operator

- The length of the array can be declared by using the LENGTHOF operator.
- The LENGTHOF operator indicates how many elements are there in an array.
- This operator instructs the assembler to calculate the length of the array at assembly time.
- Then, every time the length of the array is changed, the assembler would recalculate the length of the array.

Indexing Using esi and edi Register (Cont.)

SIZEOF Operator

- The size of the array can be declared by using the SIZEOF operator.
- The SIZEOF operator indicates how many bytes are there in an array.
- This operator instructs the assembler to calculate the size of the array at assembly time.
- Then, every time the size of the array is changed, the assembler would recalculate the size of the array.

Indexing Using esi and edi Register (Cont.)

- Using both the LENGTHOF and SIZEOF operators, the previous code segment could be rewritten as follow.

```
mov ecx,lengthof numary ; load ecx with length of numary
sar ecx,1                ; divide ecx by 2, of times to loop
lea esi,numary+0         ; load address of numary into esi
mov edi,esi              ; move contents of esi to edi
mov eax,sizeof numary   ; load eax with size of numary
sub eax,4                ; decrement eax by four
add edi,eax              ; add eax to edi for ending address of array
.repeat
mov eax,[esi]            ; move contents where esi is pointing to eax
xchg eax,[edi]           ; exchange eax and where edi is pointing
mov [esi],eax            ; move eax to where edi is pointing
add esi,4                ; add four to esi for next element
sub edi,4                ; subtract four from edi for next element
.untilcxz
```

Sequential Search

- Assuming that the data has already been entered into an array, the number of elements in the array is known, and there are no duplicates in the array. Determine whether the data being searched for is in the array by using sequential search.

Sequential Search (Cont.)

- The equivalent C code would be as follow.

```
int arry[20],n=20,i,number,found;
printf("\n%s","Enter the integer to be found: ");
scanf("%d",&number);
i=0;
found=0;
while(i<n && !found)
    if(number==arry[i])
        found=-1;
    else
        i++;
if (found)
    printf("\n%s\n\n", "The integer was found");
else
    printf("\n%s\n\n","The integer was not found");
```

Sequential Search (Cont.)

- The equivalent MASM code segment would be as follow.

```
.data
msg1fmt    byte "%s",0
msg2fmt    byte 0Ah,"%s",0Ah,0Ah,0
inlfmt     byte "%d",0
msg1       byte "Enter the integer to be found: ",0
msg2       byte "The integer was found",0
msg3       byte "The integer was not found",0
array      sdword 20 dup(?)
n          sdword 20
number     sdword ?
found      sbyte ?

.code
INVOKE printf, ADDR msg1fmt,ADDR msg1
INVOKE scanf, ADDR inlfmt, ADDR number
mov ebx,0           ; initialize ebx to 0
mov ecx,0           ; initialize ecx to 0
mov edx,number     ; load edx with number
mov found,0        ; initialize found to 0
.while(ecx<n && !found)
.if(edx==array[ebx])
mov found,-1       ; set found to -1
.else
add ebx, 4         ; increment ebx by 4
.endif
inc ecx           ; increment ecx by 1
.endw
.if(found)
INVOKE printf, ADDR msg2fmt, ADDR msg2
.else
INVOKE printf, ADDR msg3fmt, ADDR msg3
.endif
```

Complete Program: Implementing a Queue

- The implementation of a queue provides an excellent opportunity to demonstrate the use of an array and indexing.
- Consider the C and MASM programs for the given situations. The main program uses a sentinel-controlled loop to continue to iterate until the letter s is input, which stands for stop. Then for each iteration of the loop, it checks for the letter e for enqueue or d for dequeue, otherwise an appropriate error message is output.

Complete Program: Implementing a Queue

- The equivalent C code would be as follow.

```
#include <stdio.h>
const int n=3;
int queue[3],number,front=0,rear=0,count=0;
char command;
int main() {
    void enqueue();
    void dequeue();
    printf("\n%s","Enter a command, e, d, or s: ");
    scanf("%s",&command);
    while (command != 's'){
        if (command=='e'){
            printf("\n%s","Enter a positive integer: ");
            scanf("%d",&number);
            enqueue();
        }
        else
            if (command=='d'){
                dequeue();
                if (number>0)
                    printf("\n%s%d\n","The integer is: ",number);
                else
                    printf("\n%s","Invalid entry, try again");
                printf("\n%s","Enter a command, e, d, or s: ");
                scanf("%s",&command);
            }
        printf("\n");
        return 0;
    }
}

void enqueue(){
    if (count<n){
        count++;
        queue[rear]=number;
        rear=(rear+1)%n;
    }
    else
        printf("\n%s\n","Error: Queue is full");
}

void dequeue(){
    if (count>0){
        count--;
        number=queue[front];
        front=(front+1)%n;
    }
    else{
        printf("\n%s\n","Error: Queue is empty");
        number =-1;
    }
}
```

Complete Program: Implementing a Queue

- The equivalent MASM code would be as follows.

```

        .listall
        .386
        .model flat,c
        .stack 100h

      pop ecx                 ; restore ecx
      .untilcxz
      INVOKE printf, ADDR msg5fmt
      .endif
      ret
      endp
      main
end
```

Summary

- The DUP operator allows for the declaration of large initialized or uninitialized arrays.
- The ebx register can be used as an index for an array.
- When dealing with arrays of sdword, remember to increase by 4 instead of 1 because signed double word takes up 4 bytes.
- Use square brackets [] around the ebx, esi, and edi registers, not to get the contents of the register but rather to get the contents of the memory location to which they are indexing or pointing.

Implementing Queue and Selection Sort

Implementing a Queue

- The implementation of the given MASM program for a queue is described below:

```
.listall
.386
.model flat,c
.stack 100h
scanf PROTO arg2:Ptr Byte, inputlist:VARARG
printf PROTO arg1:Ptr Byte, printlist:VARARG
.data
in1fmt byte "%s",0
in2fmt byte "%d",0
msg1fmt byte 0Ah,"%s",0
msg3fmt byte 0Ah,"%s%d",0Ah,0
msg4fmt byte 0Ah,0
errrft byte 0Ah,"%s",0Ah,0
msg1 byte "Enter a command, e, d, or s: ",0
msg2 byte "Enter a positive integer: ",0
msg3 byte "The integer is: ",0
errmsg1 byte "Error: Invalid entry, try again",0
errmsg2 byte "Error: Queue is full",0
errmsg3 byte "Error: Queue is empty",0
queue sdword 3 dup(?)
command sdword ?
number sdword ?
count sdword 0
.code
enqueue macro
.if count < lengthof queue
inc count ; increment count
mov eax,number ; load eax with number
mov [edi],eax ; store eax in rear
```

Microprocessor Programming

Practical Assignments (Instructions)

Assignment 1

- Write a complete assembly program using the code segment given below and show the output message.

```
.data
msg1fmt byte 0Ah,"%s",0
msg2fmt byte 0Ah,"%s",0Ah,0Ah,0
msg3fmt byte " %d",0Ah,0Ah, 0
in1fmt  byte "%d",0
msg1    byte "Enter the number of integers to be input: ",0
msg2    byte "Enter an integer: ",0
msg3    byte "Reversed",0
msg4    byte "No data entered."
n       sdword ?
arry    sdword 20 dup(?)

.code
INVOKE printf, ADDR msg1fmt,ADDR msg1
INVOKE scanf, ADDR in1fmt, ADDR n
mov ecx,n                ; initialize ecx to n
mov ebx,0                ; initialize ebx to 0
.if ecx>0
.repeat
push ecx                 ; save ecx
INVOKE printf, ADDR msg1fmt, ADDR msg2
INVOKE scanf, ADDR in1fmt, ADDR arry[ebx]
pop ecx                 ; restore ecx
add ebx,4               ; increment ebx by 4
.untilcxz
INVOKE printf, ADDR msg2fmt, ADDR msg3
mov ecx,n                ; initialize ecx to n
sub ebx,4               ; subtract 4 from ebx
.repeat
push ecx                 ; save ecx
INVOKE printf, ADDR msg3fmt,arry[ebx]
pop ecx                 ; restore ecx
sub ebx,4               ; decrement ebx by 4
.untilcxz
.else
INVOKE printf, ADDR msg2fmt, ADDR msg4
.endif
```

Assignment 2

- Write a complete assembly program using the code segment given below and show the output messages.

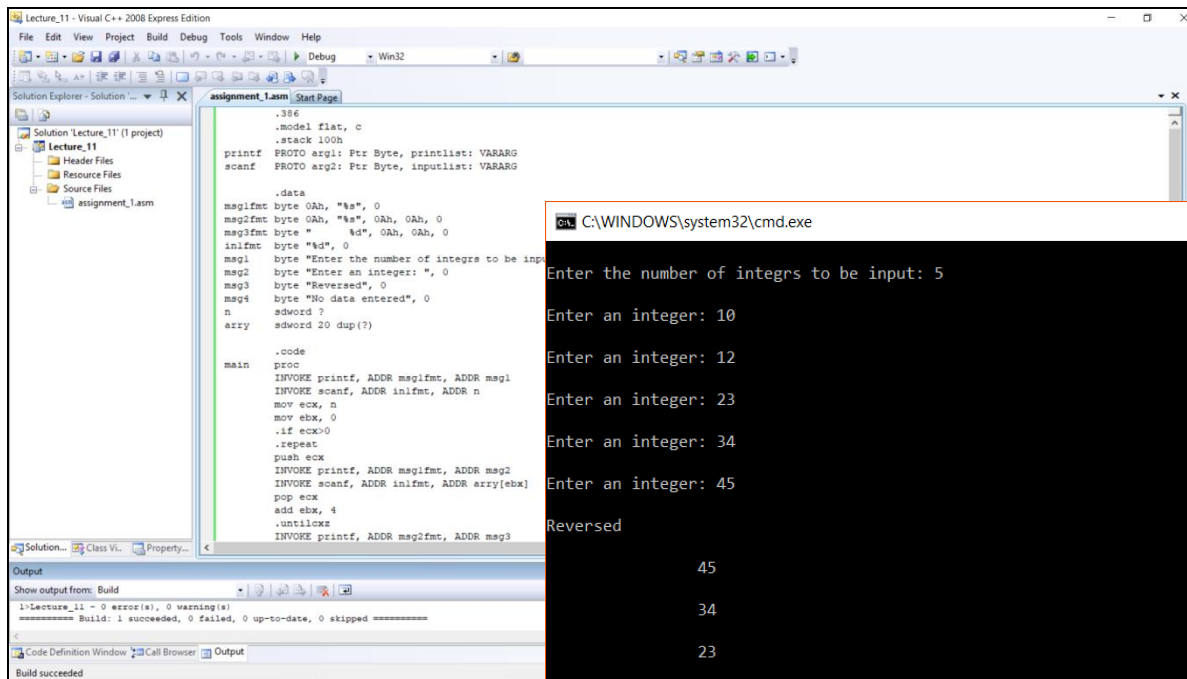

```
.data
msg1fmt byte "%s",0
msg2fmt byte 0Ah,"%s",0Ah,0Ah,0
in1fmt byte "%d",0
msg1 byte "Enter the integer to be found: ",0
msg2 byte "The integer was found",0
msg3 byte "The integer was not found",0
arry sdword 1,2,3,4,5
n sdword 5
number sdword ?
found sbyte ?
.code
INVOKE printf, ADDR msg1fmt,ADDR msg1
INVOKE scanf, ADDR in1fmt, ADDR number
mov ebx,0          ; initialize ebx to 0
mov ecx,0          ; initialize ecx to 0
mov edx,number    ; load edx with number
mov found,0       ; initialize found to 0
.while(ecx<n && !found)
.if(edx==arry[ebx])
mov found,-1      ; set found to -1
.else
add ebx, 4        ; increment ebx by 4
.endif
inc ecx           ; increment ecx by 1
.endw
.if(found)
INVOKE printf, ADDR msg2fmt, ADDR msg2
.else
INVOKE printf, ADDR msg3fmt, ADDR msg3
.endif
```

Microprocessor Programming

Practical Assignments (Report)

Assignment 1

- A complete assembly program and its output are described below:

The screenshot shows the Visual Studio 2008 Express Edition interface. The main window displays the assembly code for 'assignment_1.asm'. The code includes directives for flat model, stack size, and data section. It defines messages for input and output, and a main procedure that reads integers, reverses them, and prints the result. The output window at the bottom shows the build process and the program's execution output.

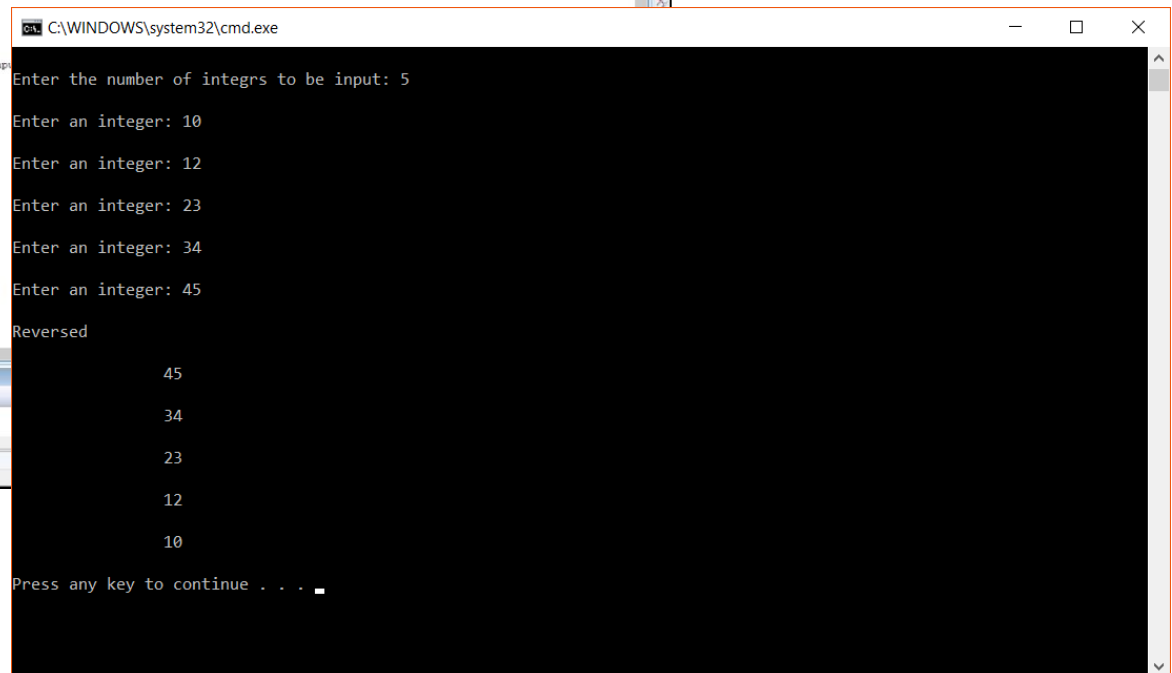

```
.386
.model flat, c
.stack 100h
printf PROTO arg1: Ptr Byte, printlist: VARARG
scanf PROTO arg2: Ptr Byte, inputlist: VARARG

.data
msg1fmt byte 0Ah, "%s", 0
msg2fmt byte 0Ah, "%s", 0Ah, 0Ah, 0
msg1fmt byte " %d", 0Ah, 0Ah, 0
inifmt byte "%d", 0
msg1 byte "Enter the number of integers to be input: ", 0
msg2 byte "Enter an integer: ", 0
msg3 byte "Reversed", 0
msg4 byte "No data entered", 0
n sdword ?
array sdword ?

.code
main
proc
    INVOKE printf, ADDR msg1fmt, ADDR msg1
    INVOKE scanf, ADDR inifmt, ADDR n
    mov ecx, n
    mov ebx, 0
    .if ecx>0
    .repeat
    push ecx
    INVOKE printf, ADDR msg1fmt, ADDR msg2
    INVOKE scanf, ADDR inifmt, ADDR array[ebx]
    pop ecx
    add ebx, 4
    .until ecx
    INVOKE printf, ADDR msg2fmt, ADDR msg3
```

Output

```
l>Lecture_11 - 0 error(s), 0 warning(s)
===== Build: 1 succeeded, 0 failed, 0 up-to-date, 0 skipped =====
Code Definition Window Call Browser Output
Build succeeded
```

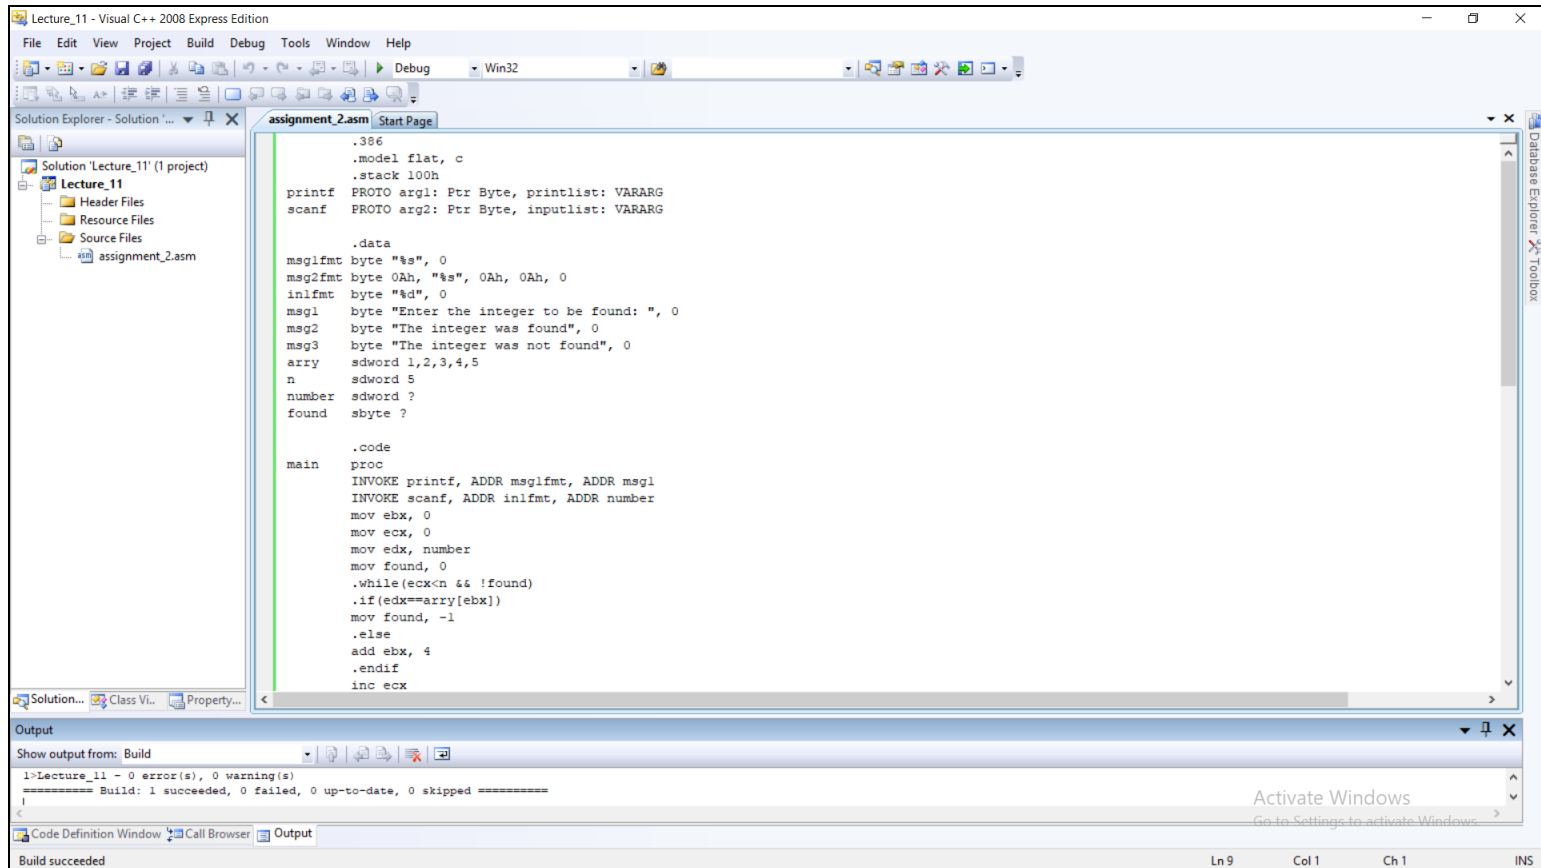

The screenshot shows a Windows command prompt window titled 'C:\WINDOWS\system32\cmd.exe'. The program's output is displayed, showing the user entering the number of integers (5) and then five integers (10, 12, 23, 34, 45). The program then prints the reversed integers (45, 34, 23, 12, 10) and prompts the user to press any key to continue.

```
C:\WINDOWS\system32\cmd.exe
Enter the number of integers to be input: 5
Enter an integer: 10
Enter an integer: 12
Enter an integer: 23
Enter an integer: 34
Enter an integer: 45
Reversed
45
34
23
12
10
Press any key to continue . . .
```

Assignment 2

- A complete assembly program is described below:

```
.386
.model flat, c
.stack 100h

printf PROTO arg1: Ptr Byte, printlist: VARARG
scanf  PROTO arg2: Ptr Byte, inputlist: VARARG

.data
msg1fmt byte "%s", 0
msg2fmt byte 0Ah, "%s", 0Ah, 0Ah, 0
inlfmt  byte "%d", 0
msg1    byte "Enter the integer to be found: ", 0
msg2    byte "The integer was found", 0
msg3    byte "The integer was not found", 0
array   sdword 1,2,3,4,5
n        sdword 5
number  sdword ?
found    sbyte ?

.code
main     proc
        INVOKE printf, ADDR msg1fmt, ADDR msg1
        INVOKE scanf, ADDR inlfmt, ADDR number
        mov ebx, 0
        mov ecx, 0
        mov edx, number
        mov found, 0
        .while(ecx<n && !found)
        .if(edx==array[ebx])
        mov found, -1
        .else
        add ebx, 4
        .endif
        inc ecx
```

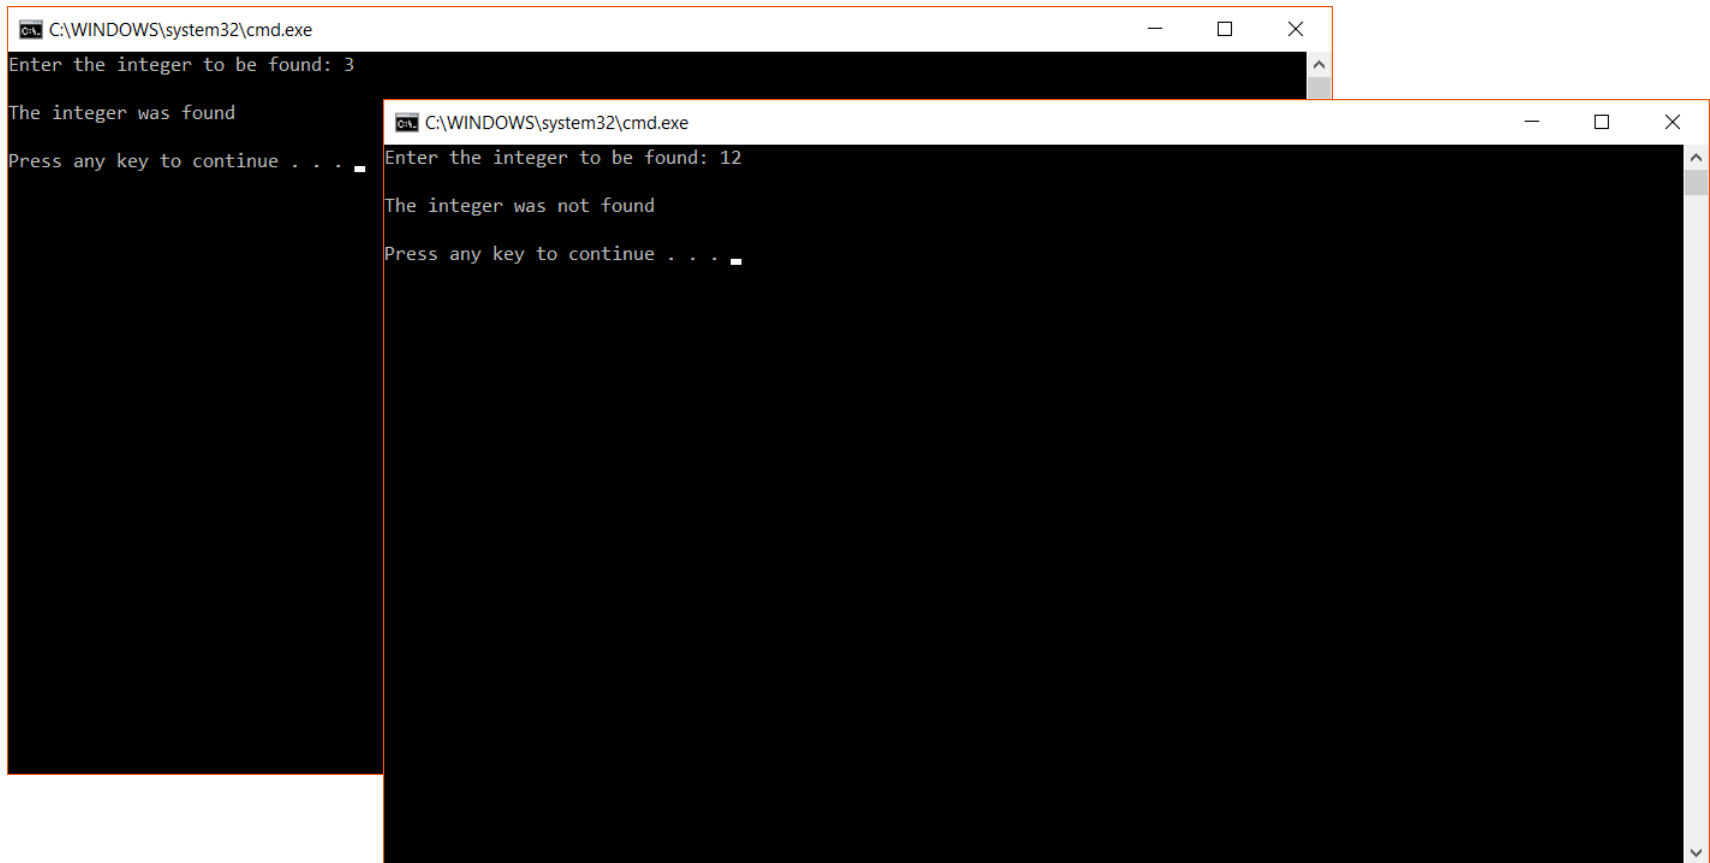

Output

```
Show output from: Build
1>Lecture_11 - 0 error(s), 0 warning(s)
===== Build: 1 succeeded, 0 failed, 0 up-to-date, 0 skipped =====
!
```

Build succeeded

Assignment 2

- The outputs for the complete assembly program are described below:

The image shows two overlapping Windows command prompt windows. The top window has the title bar 'C:\WINDOWS\system32\cmd.exe' and contains the following text: 'Enter the integer to be found: 3', 'The integer was found', and 'Press any key to continue . . .'. The bottom window also has the title bar 'C:\WINDOWS\system32\cmd.exe' and contains the following text: 'Enter the integer to be found: 12', 'The integer was not found', and 'Press any key to continue . . .'. Both windows have a black background with white text.
